Maxwell Equations

In Yee algorithm, using Gaussian unit style with $c = 1$, i.e.

$$\nabla \times E = -\frac{1}{c}\frac{\partial B}{\partial t} = -\frac{\partial B}{\partial \tilde{t}} \tag{0.1}$$

$$\nabla \times B = \frac{4\pi}{c}J + \frac{1}{c}\frac{\partial E}{\partial t} = 4\pi\tilde{J} + \frac{\partial E}{\partial \tilde{t}}. \tag{0.2}$$

I chose to keep cm as the length unit, so that the subsequent two Maxwell equations are unaffected:

$$\nabla \cdot E = 4\pi\rho \tag{0.3}$$

$$\nabla \cdot B = 0. \tag{0.4}$$

This means that the time has the unit of (1 cm) / (speed of light in seconds), i.e.

$$1\tilde{s} = \frac{1\ \text{cm}}{c_0} \approx 3.3 \times 10^{-11}\ \text{s}, \tag{0.5}$$

where $c_0 \approx 2.9979 \times 10^{10}$ is the speed of light in unit of cm/s.

Velocity, acceleration, and current density

The velocity $\tilde{v}$ is now normalized automatically to the speed of light, since it is measured in cm / (distance light travels in 1 cm). Namely,

$$\tilde{v} = \frac{v}{c_0 \text{cm/s}}. \tag{0.6}$$

We then have the Lorentz acceleration as

$$a = \frac{1}{c_0^2}\frac{q}{m}\left(E + \tilde{v} \times B\right) \tag{0.7}$$

$$\approx 1.1 \times 10^{-21}\frac{q}{m}\left(E + \tilde{v} \times B\right). \tag{0.8}$$

The small acceleration reflects the timescale separation between light waves and plasma motion.
Finally, current densities should be calculated in statC/cm$^2\tilde{s}$.

Charge, Mass, and Field

It is convenient to normalize charge q to electron charge e, and normalize mass m to electron mass m_e. Namely,

$$\tilde{q} = \frac{q}{e},\ \tilde{m} = \frac{m}{m_e}. \tag{0.9}$$

Recall the value

$$\frac{e}{m_e} \approx 5.2728 \times 10^{17}\text{statC/g}. \tag{0.10}$$

Having normalized charge and mass, it is convenient to normalize the electric field E to kilo statV/cm (KstatV/cm), and normalize the magnetic field B to kilo Gauss (KG). Namely,

$$\tilde{E} = \frac{E}{\text{KstatV/cm}},\ \ \tilde{B} = \frac{B}{\text{KG}}. \tag{0.11}$$

It is useful to note

$$\frac{1 \cdot \text{KstatV/cm}}{c_0 \cdot \text{KG}} = 1. \tag{0.12}$$

With such normalization, there is no large or small coefficient in the Newton's equation with Lorentz force. Explicitly, we have

$$\tilde{a} = \frac{a}{\text{cm} \cdot \tilde{s}^{-2}} \tag{0.13}$$

$$= \frac{\tilde{q}}{\tilde{m}}(\tilde{E} + \tilde{v} \times \tilde{B}) \times \frac{e \cdot \text{Kstat/cm}}{m_e \cdot \text{cm} \cdot \tilde{s}^{-2}} \tag{0.14}$$

$$\approx 0.58668774\frac{\tilde{q}}{\tilde{m}}(\tilde{E} + \tilde{v} \times \tilde{B}). \tag{0.15}$$

To get a sense of how large the electric and magnetic fields are, it is useful to note

$$\tilde{E} = 1 \quad \leftrightarrow \quad E \approx 299.79\text{KV/cm}, \tag{0.16}$$

$$\tilde{B} = 1 \quad \leftrightarrow \quad B = 0.1\text{T}, \tag{0.17}$$

where KV/cm stands for kilo volte/cm, and T stands for tesla. Notice that a constant field $\tilde{E} = 1$ is a very large electric field, which can accelerate an electron to relativistic velocity within 1 $\tilde{s}$. In comparison, a constant field $\tilde{B} = 1$ is moderate magnetic field that can be easily produced in laboratory.
